CHAPTER 23

SORTING

Objectives

- To study and analyze time complexity of various sorting algorithms (§§23.2–23.7).
- To design, implement, and analyze insertion sort (§23.2).
- To design, implement, and analyze bubble sort (§23.3).
- To design, implement, and analyze merge sort (§23.4).
- To design, implement, and analyze quick sort (§23.5).
- To design and implement a binary heap (§23.6).
- To design, implement, and analyze heap sort (§23.6).
- To design, implement, and analyze bucket and radix sorts (§23.7).
- To design, implement, and analyze external sort for files that have a large amount of data (§23.8).

23.1 Introduction

Sorting algorithms are good examples for studying algorithm design and analysis.

When president Barack Obama visited Google in 2007, the Google CEO Eric Schmidt asked Obama the most efficient way to sort a million 32-bit integers (www.youtube.com/watch?v=k4RRi_ntQc8). Obama answered that the bubble sort would be the wrong way to go. Was he right? We will examine different sorting algorithms in this chapter and see if he was correct.

Sorting is a classic subject in computer science. There are three reasons to study sorting algorithms.

- First, sorting algorithms illustrate many creative approaches to problem solving, and these approaches can be applied to solve other problems.
- Second, sorting algorithms are good for practicing fundamental programming techniques using selection statements, loops, methods, and arrays.
- Third, sorting algorithms are excellent examples to demonstrate algorithm performance.

The data to be sorted might be integers, doubles, characters, or objects. Section 7.11, Sorting Arrays, presented selection sort. The selection-sort algorithm was extended to sort an array of objects in Section 19.5, Case Study: Sorting an Array of Objects. The Java API contains several overloaded sort methods for sorting primitive-type values and objects in the <code>java.util.Arrays</code> and <code>java.util.Collections</code> classes. For simplicity, this chapter assumes

- 1. data to be sorted are integers,
- 2. data are stored in an array, and
- 3. data are sorted in ascending order.

The programs can be easily modified to sort other types of data, to sort in descending order, or to sort data in an ArrayList or a LinkedList.

There are many algorithms for sorting. You have already learned selection sort. This chapter introduces insertion sort, bubble sort, merge sort, quick sort, bucket sort, radix sort, and external sort.

23.2 Insertion Sort

The insertion-sort algorithm sorts a list of values by repeatedly inserting a new element into a sorted sublist until the whole list is sorted.

Figure 23.1 shows how to sort a list {2, 9, 5, 4, 8, 1, 6} using insertion sort. For an interactive demo on how insertion sort works, go to liveexample.pearsoncmg.com/dsanimation/Insertion-SortNeweBook.html.

The algorithm can be described as follows:

```
for (int i = 1; i < list.length; i++) {
  insert list[i] into a sorted sublist list[0..i-1] so that
  list[0..i] is sorted.
}</pre>
```

To insert list[i] into list[0..i-1], save list[i] into a temporary variable, say currentElement. Move list[i-1] to list[i] if list[i-1] > currentElement, move list[i-2] to list[i-1] if list[i-2] > currentElement, and so on, until list[i-k] <= currentElement or k > i (we pass the first element of the sorted list). Assign currentElement to list[i-k+1]. For example, to insert 4 into {2, 5, 9} in Step 4 in Figure 23.2, move list[2] (9) to list[3] since 9 > 4 and move list[1] (5) to list[2] since 5 > 4. Finally, move currentElement (4) to list[1].

why study sorting?

what data to sort?

insertion-sort animation on Companion Website

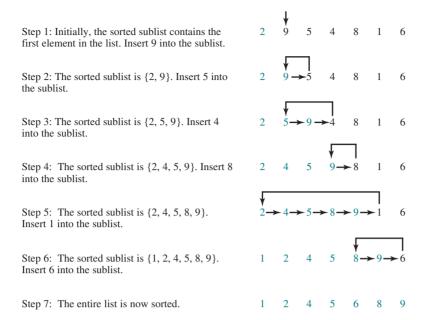

FIGURE 23.1 Insertion sort repeatedly inserts a new element into a sorted sublist.

FIGURE 23.2 A new element is inserted into a sorted sublist.

The algorithm can be expanded and implemented as in Listing 23.1.

LISTING 23.1 InsertionSort.java

```
public class InsertionSort {
 2
      /** The method for sorting the numbers */
 3
      public static void insertionSort(int[] list) {
 4
        for (int i = 1; i < list.length; i++) {</pre>
 5
          /** Insert list[i] into a sorted sublist list[0..i-1] so that
 6
               list[0..i] is sorted. */
 7
          int currentElement = list[i];
 8
          int k;
 9
          for (k = i - 1; k \ge 0 \&\& list[k] > currentElement; k--) {
                                                                                shift
10
            list[k + 1] = list[k];
11
12
          // Insert the current element into list[k + 1]
13
14
          list[k + 1] = currentElement;
                                                                                insert
15
16
      }
17
    }
```

insertion-sort time

complexity

The insertionSort(int[] list) method sorts an array of int elements. The method is implemented with a nested for loop. The outer loop (with the loop control variable i) (line 4) is iterated in order to obtain a sorted sublist, which ranges from list[0] to list[i]. The inner loop (with the loop control variable k) inserts list[i] into the sublist from list[0] to list[i-1].

To better understand this method, trace it with the following statements:

```
int[] list = {1, 9, 4, 6, 5, -4};
InsertionSort.insertionSort(list);
```

The insertion-sort algorithm presented here sorts a list of elements by repeatedly inserting a new element into a sorted partial array until the whole array is sorted. At the kth iteration, to insert an element into an array of size k, it may take k comparisons to find the insertion position and k moves to insert the element. Let T(n) denote the complexity for insertion sort, and c denote the total number of other operations such as assignments and additional comparisons in each iteration. Thus,

$$T(n) = (2+c) + (2 \times 2 + c) + \dots + (2 \times (n-1) + c)$$

$$= 2(1+2+\dots+n-1) + c(n-1)$$

$$= 2\frac{(n-1)n}{2} + cn - c = n^2 - n + cn - c$$

$$= O(n^2)$$

Therefore, the complexity of the insertion-sort algorithm is $O(n^2)$. Hence, the selection and insertion sorts are of the same time complexity.

- **23.2.1** Describe how an insertion sort works. What is the time complexity for an insertion sort?
- **23.2.2** Use Figure 23.1 as an example to show how to apply an insertion sort on {45, 11, 50, 59, 60, 2, 4, 7, 10}.
- **23.2.3** If a list is already sorted, how many comparisons will the **insertionSort** method perform?

23.3 Bubble Sort

A bubble sort sorts the array in multiple passes. Each pass successively swaps the neighboring elements if the elements are not in order.

The bubble-sort algorithm makes several passes through the array. On each pass, successive neighboring pairs are compared. If a pair is in decreasing order, its values are swapped; otherwise, the values remain unchanged. The technique is called a *bubble sort* or *sinking sort* because the smaller values gradually "bubble" their way to the top and the larger values sink to the bottom. After the first pass, the last element becomes the largest in the array. After the second pass, the second-to-last element becomes the second largest in the array. This process is continued until all elements are sorted.

Figure 23.3a shows the first pass of a bubble sort on an array of six elements (2 9 5 4 8 1). Compare the elements in the first pair (2 and 9) and no swap is needed because they are already in order. Compare the elements in the second pair (9 and 5) and swap 9 with 5 because 9 is greater than 5. Compare the elements in the third pair (9 and 4) and swap 9 with 4. Compare the elements in the fourth pair (9 and 8) and swap 9 with 8. Compare the elements in the fifth pair (9 and 1) and swap 9 with 1. The pairs being compared are highlighted and the numbers already sorted are italicized in Figure 23.3. For an interactive demo on how bubble sort works, go to liveexample.pearsoncmg.com/dsanimation/BubbleSort-NeweBook.html.

bubble sort

bubble-sort illustration

bubble sort animation on the Companion Website

```
2 9 5 4 8 1
              2 5 4 8 1 9
                             2 4 5 1 8 9
              2 4 5 8 1 9
2 5 9 4 8 1
                              2 4 5 1 8 9
                                             2 1 4 5 8 9
                              2 4 1 5 8 9
2 5 4 9 8 1
              2 4 5 8 1 9
2 5 4 8 9 1
              2 4 5 1 8 9
2 5 4 8 1 9
 (a) 1st pass
               (b) 2nd pass
                               (c) 3rd pass
                                              (d) 4th pass
                                                             (e) 5th pass
```

FIGURE 23.3 Each pass compares and orders the pairs of elements sequentially.

The first pass places the largest number (9) as the last in the array. In the second pass, as shown in Figure 23.3b, you compare and order pairs of elements sequentially. There is no need to consider the last pair because the last element in the array is already the largest. In the third pass, as shown in Figure 23.3c, you compare and order pairs of elements sequentially except the last two elements because they are already in order. Thus, in the kth pass, you don't need to consider the last k-1 elements because they are already ordered.

The algorithm for a bubble sort is described in Listing 23.2.

algorithm

LISTING 23.2 Bubble-Sort Algorithm

```
1  for (int k = 1; k < list.length; k++) {
2    // Perform the kth pass
3    for (int i = 0; i < list.length - k; i++) {
4        if (list[i] > list[i + 1])
5            swap list[i] with list[i + 1];
6        }
7    }
```

Note if no swap takes place in a pass, there is no need to perform the next pass because all the elements are already sorted. You can use this property to improve the algorithm in Listing 23.2, as in Listing 23.3.

LISTING 23.3 Improved Bubble-Sort Algorithm

```
boolean needNextPass = true;
   for (int k = 1; k < list.length && needNextPass; k++) {</pre>
      // Array may be sorted and next pass not needed
 4
      needNextPass = false;
 5
      // Perform the kth pass
 6
      for (int i = 0; i < list.length - k; i++) {</pre>
 7
        if (list[i] > list[i + 1]) {
 8
          swap list[i] with list[i + 1];
 9
          needNextPass = true; // Next pass still needed
10
        }
11
      }
12
    }
```

The algorithm can be implemented in Listing 23.4.

LISTING 23.4 BubbleSort.java

```
public class BubbleSort {
    /** Bubble sort method */
public static void bubbleSort(int[] list) {
    boolean needNextPass = true;

for (int k = 1; k < list.length && needNextPass; k++) {
    // Array may be sorted and next pass not needed needNextPass = false;
    for (int i = 0; i < list.length - k; i++) {</pre>
```

perform one pass

```
10
            if (list[i] > list[i + 1]) {
11
              // Swap list[i] with list[i + 1]
12
              int temp = list[i];
13
              list[i] = list[i + 1];
14
              list[i + 1] = temp;
15
              needNextPass = true; // Next pass still needed
16
17
18
          }
19
        }
20
      }
21
22
      /** A test method */
23
      public static void main(String[] args) {
        int[] list = {2, 3, 2, 5, 6, 1, -2, 3, 14, 12};
24
25
        bubbleSort(list);
        for (int i = 0; i < list.length; i++)</pre>
26
27
          System.out.print(list[i] + " ");
28
      }
29
   }
```

-2 1 2 2 3 3 5 6 12 14

In the best case, the bubble-sort algorithm needs just the first pass to find that the array is already sorted—no next pass is needed. Since the number of comparisons is n-1 in the first pass, the best-case time for a bubble sort is O(n).

In the worst case, the bubble-sort algorithm requires n-1 passes. The first pass makes n-1 comparisons, the second pass makes n-2 comparisons, and so on; the last pass makes 1 comparison. Thus, the total number of comparisons is as follows:

$$(n-1) + (n-2) + \cdots + 2 + 1$$

= $\frac{(n-1)n}{2} = \frac{n^2}{2} - \frac{n}{2} = O(n^2)$

Therefore, the worst-case time for a bubble sort is $O(n^2)$.

- **23.3.1** Describe how a bubble sort works. What is the time complexity for a bubble sort?
- **23.3.2** Use Figure 23.3 as an example to show how to apply a bubble sort on {45, 11, 50, 59, 60, 2, 4, 7, 10}.
- **23.3.3** If a list is already sorted, how many comparisons will the **bubbleSort** method perform?

23.4 Merge Sort

The merge-sort algorithm can be described recursively as follows: The algorithm divides the array into two halves and applies a merge sort on each half recursively. After the two halves are sorted, the algorithm then merges them.

merge sort The algorithm for a *merge sort* is given in Listing 23.5.

LISTING 23.5 Merge-Sort Algorithm

bubble-sort time complexity

Figure 23.4 illustrates a merge sort of an array of eight elements (29548167). The original array is split into (2954) and (8167). Apply a merge sort on these two subarrays recursively to split (2954) into (29) and (54) and (8167) into (81) and (67). This process continues until the subarray contains only one element. For example, array (29) is split into the subarrays (2) and (9). Since array (2) contains a single element, it cannot be further split. Now merge (2) with (9) into a new sorted array (29) and (5) with (4) into a new sorted array (45). Merge (29) with (45) into a new sorted array (2459) and finally merge (2459) with (1678) into a new sorted array (12456789).

merge-sort illustration

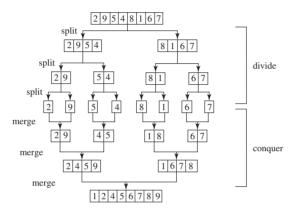

FIGURE 23.4 Merge sort employs a divide-and-conquer approach to sort the array.

The recursive call continues dividing the array into subarrays until each subarray contains only one element. The algorithm then merges these small subarrays into larger sorted subarrays until one sorted array results.

The merge-sort algorithm is implemented in Listing 23.6.

LISTING 23.6 MergeSort.java

```
public class MergeSort {
 2
      /** The method for sorting the numbers */
 3
      public static void mergeSort(int[] list) {
 4
        if (list.length > 1) {
                                                                                base case
 5
          // Merge sort the first half
 6
          int[] firstHalf = new int[list.length / 2];
 7
          System.arraycopy(list, 0, firstHalf, 0, list.length / 2);
 8
          mergeSort(firstHalf);
                                                                                sort first half
 9
10
          // Merge sort the second half
11
          int secondHalfLength = list.length - list.length / 2;
12
          int[] secondHalf = new int[secondHalfLength];
13
          System.arraycopy(list, list.length / 2,
14
            secondHalf, 0, secondHalfLength);
15
          mergeSort(secondHalf);
                                                                                sort second half
16
17
          // Merge firstHalf with secondHalf into list
18
          merge(firstHalf, secondHalf, list);
                                                                                merge two halves
19
        }
20
      }
21
22
      /** Merge two sorted lists */
23
      public static void merge(int[] list1, int[] list2, int[] temp) {
24
        int current1 = 0; // Current index in list1
```

```
list1 to temp
list2 to temp
rest of list1 to temp
rest of list2 to temp
```

merge animation on Companion Website

```
25
        int current2 = 0: // Current index in list2
26
        int current3 = 0; // Current index in temp
27
        while (current1 < list1.length && current2 < list2.length) {</pre>
28
          if (list1[current1] < list2[current2])</pre>
29
30
             temp[current3++] = list1[current1++];
31
          else
32
             temp[current3++] = list2[current2++];
33
34
35
        while (current1 < list1.length)</pre>
          temp[current3++] = list1[current1++];
36
37
38
        while (current2 < list2.length)</pre>
39
          temp[current3++] = list2[current2++];
40
41
42
      /** A test method */
43
      public static void main(String[] args) {
44
        int[] list = {2, 3, 2, 5, 6, 1, -2, 3, 14, 12};
45
        mergeSort(list);
        for (int i = 0; i < list.length; i++)</pre>
46
47
          System.out.print(list[i] + " ");
48
    }
49
```

The mergeSort method (lines 3–20) creates a new array firstHalf, which is a copy of the first half of list (line 7). The algorithm invokes mergeSort recursively on firstHalf (line 8). The length of the firstHalf is list.length / 2 and the length of the second-Half is list.length - list.length / 2. The new array secondHalf was created to contain the second part of the original array list. The algorithm invokes mergeSort recursively on secondHalf (line 15). After firstHalf and secondHalf are sorted, they are merged to list (line 18). Thus, array list is now sorted.

The merge method (lines 23–40) merges two sorted arrays list1 and list2 into array temp. current1 and current2 point to the current element to be considered in list1 and list2 (lines 24–26). The method repeatedly compares the current elements from list1 and list2 and moves the smaller one to temp. current1 is increased by 1 (line 30) if the smaller one is in list1, and current2 is increased by 1 (line 32) if the smaller one is in list2. Finally, all the elements in one of the lists are moved to temp. If there are still unmoved elements in list1, copy them to temp (lines 35–36). If there are still unmoved elements in list2, copy them to temp (lines 38–39).

Figure 23.5 illustrates how to merge the two arrays **list1** (2 4 5 9) and **list2** (1 6 7 8). Initially, the current elements to be considered in the arrays are 2 and 1. Compare

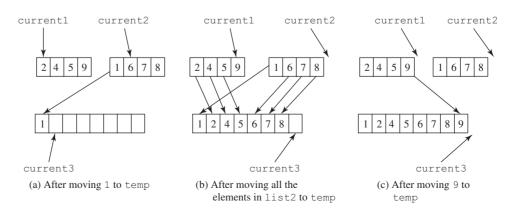

FIGURE 23.5 Two sorted arrays are merged into one sorted array.

them and move the smaller element 1 to **temp**, as shown in Figure 23.5a. **current2** and **current3** are increased by 1. Continue to compare the current elements in the two arrays and move the smaller one to **temp** until one of the arrays is completely moved. As shown in Figure 23.5b, all the elements in **list2** are moved to **temp** and **current1** points to element 9 in **list1**. Copy 9 to **temp**, as shown in Figure 23.5c. For an interactive demo on how merge works, go to liveexample.pearsoncmg.com/dsanimation/Merge SortNeweBook.html.

The **mergeSort** method creates two temporary arrays (lines 6 and 12) during the dividing process, copies the first half and the second half of the array into the temporary arrays (lines 7 and 13), sorts the temporary arrays (lines 8 and 15), then merges them into the original array (line 18), as shown in Figure 23.6a. You can rewrite the code to recursively sort the first half of the array and the second half of the array without creating new temporary arrays, then merge the two arrays into a temporary array and copy its contents to the original array, as shown in Figure 23.6b. This is left for you to do in Programming Exercise 23.20.

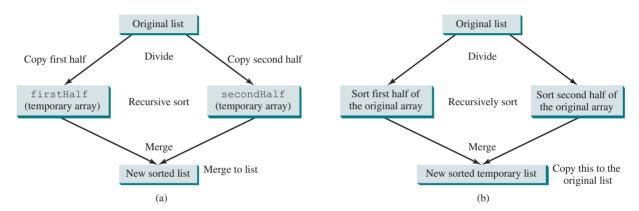

FIGURE 23.6 Temporary arrays are created to support a merge sort.

Note

A merge sort can be implemented efficiently using parallel processing. See Section 32.16, Parallel Programming, for a parallel implementation of a merge sort.

Let us analyze the running time of merge sort now. Let T(n) denote the time required for sorting an array of n elements using a merge sort. Without loss of generality, assume n is a power of 2. The merge-sort algorithm splits the array into two subarrays, sorts the subarrays using the same algorithm recursively, then merges the subarrays. Therefore,

merge-sort time complexity

$$T(n) = T\left(\frac{n}{2}\right) + T\left(\frac{n}{2}\right) + mergetime$$

The first $T\left(\frac{n}{2}\right)$ is the time for sorting the first half of the array and the second $T\left(\frac{n}{2}\right)$ is the

time for sorting the second half. To merge two subarrays, it takes at most n-1 comparisons to compare the elements from the two subarrays, and n moves to move elements to the temporary array. Thus, the total time is 2n-1. Therefore,

$$T(n) = T\left(\frac{n}{2}\right) + T\left(\frac{n}{2}\right) + 2n - 1 = O(n \log n)$$

The complexity of a merge sort is $O(n \log n)$. This algorithm is better than selection sort, insertion sort, and bubble sort because the time complexity of these algorithms is $O(n^2)$. The **sort**

 $O(n \log n)$ merge sort

method in the java.util.Arrays class is implemented using a variation of the merge-sort algorithm.

- **23.4.1** Describe how a merge sort works. What is the time complexity for a merge sort?
- **23.4.2** Use Figure 23.4 as an example to show how to apply a merge sort on {45, 11, 50, 59, 60, 2, 4, 7, 10}.
- **23.4.3** What is wrong if lines 6–15 in Listing 23.6, MergeSort.java, are replaced by the following code?

23.5 Quick Sort

A quick sort works as follows: The algorithm selects an element, called the pivot, in the array. It divides the array into two parts so all the elements in the first part are less than or equal to the pivot, and all the elements in the second part are greater than the pivot. The quick-sort algorithm is then recursively applied to the first part and then the second part.

The quick-sort algorithm, developed by C.A.R. Hoare in 1962, is described in Listing 23.7.

LISTING 23.7 Quick-Sort Algorithm

```
public static void quickSort(int[] list) {
2
      if (list.length > 1) {
3
        select a pivot;
4
        partition list into list1 and list2 such that
5
          all elements in list1 <= pivot and
6
          all elements in list2 > pivot;
7
        quickSort(list1);
8
        quickSort(list2);
9
      }
10

```

how to partition

Each partition places the pivot in the right place. It divides the list into two sublists as shown in the following figure.

```
list pivot list2
```

The selection of the pivot affects the performance of the algorithm. Ideally, the algorithm should choose the pivot that divides the two parts evenly. For simplicity, assume that the first element in the array is chosen as the pivot. (Programming Exercise 23.4 proposes an alternative strategy for selecting the pivot.)

Figure 23.7 illustrates how to sort an array (5 2 9 3 8 4 0 1 6 7) using quick sort. Choose the first element, 5, as the pivot. The array is partitioned into two parts, as shown in

sort second part

quick-sort illustration

Figure 23.7b. The highlighted pivot is placed in the right place in the array. Apply quick sort on two subarrays (4 2 1 3 0) then (8 9 6 7). The pivot 4 partitions (4 2 1 3 0) into just one subarrays (0 2 1 3), as shown in Figure 23.7c. Apply quick sort on (0 2 1 3). The pivot 0 partitions it into just one subarrays (2 1 3), as shown in Figure 23.7d. Apply quick sort on (2 1 3). The pivot 2 partitions it into (1) and (3), as shown in Figure 23.7e. Apply quick sort on (1). Since the array contains just one element, no further partition is needed.

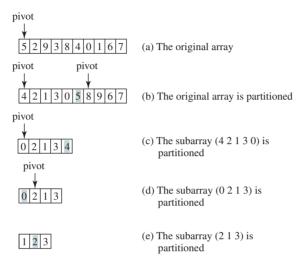

FIGURE 23.7 The quick-sort algorithm is recursively applied to subarrays.

The quick-sort algorithm is implemented in Listing 23.8. There are two overloaded **quickSort** methods in the class. The first method (line 2) is used to sort an array. The second is a helper method (line 6) that sorts a subarray with a specified range.

LISTING 23.8 QuickSort.java

```
public class QuickSort {
      public static void quickSort(int[] list) {
 2
                                                                                sort method
 3
        quickSort(list, 0, list.length - 1);

54
        quickSort(list);
55
        for (int i = 0; i < list.length; i++)</pre>
56
          System.out.print(list[i] + " ");
57
58
    }
```

```
-2 1 2 2 3 3 5 6 12 14
```

The **partition** method (lines 15–49) partitions the array **list[first..last]** using the pivot. The first element in the partial array is chosen as the pivot (line 16). Initially, **low** points to the second element in the subarrays (line 17) and **high** points to the last element in the subarrays (line 18).

Starting from the left, the method searches forward in the array for the first element that is greater than the pivot (lines 22–23), then searches from the right backward for the first element in the array that is less than or equal to the pivot (lines 26–27). It then swaps these two elements and repeats the same search and swap operations until all the elements are searched in a while loop (lines 20–35).

The method returns the new index for the pivot that divides the subarrays into two parts if the pivot has been moved (line 44). Otherwise, it returns the original index for the pivot (line 47).

Figure 23.8 illustrates how to partition an array (5 2 9 3 8 4 0 1 6 7). Choose the first element, 5, as the pivot. Initially, **low** is the index that points to element 2 and **high** points to element 7, as shown in Figure 23.8a. Advance index **low** forward to search for the first element (9) that is greater than the pivot, and move index **high** backward to search for the first element (1) that is less than or equal to the pivot, as shown in Figure 23.8b. Swap 9 with 1, as shown in Figure 23.8c. Continue the search and move **low** to point to element 8 and **high** to point to element 0, as shown in Figure 23.8d. Swap element 8 with 0, as shown in Figure 23.8e. Continue to move **low** until it passes **high**, as shown in Figure 23.8f. Now all the elements are examined. Swap

partition illustration

partition animation on Companion Website the pivot with element 4 at index high. The final partition is shown in Figure 23.8g. The index of the pivot is returned when the method is finished. For an interactive demo on how partition works, go to liveexample.pearsoncmg.com/dsanimation/QuickSortNeweBook.html.

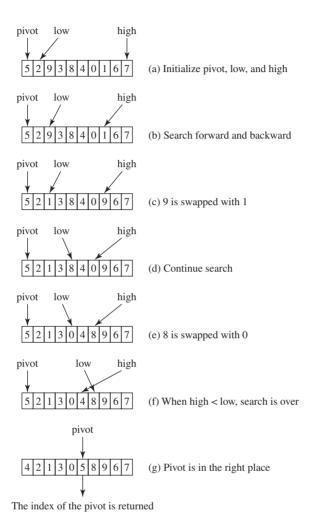

FIGURE 23.8 The **partition** method returns the index of the pivot after it is put in the correct place.

To partition an array of n elements, it takes n comparisons and n moves in the worst case. Thus, the time required for partition is O(n).

In the worst case, the pivot divides the array each time into one big subarray with the other array empty. The size of the big subarray is one less than the one before divided. The algorithm requires $(n-1)+(n-2)+\cdots+2+1=O(n^2)$ time.

In the best case, the pivot divides the array each time into two parts of about the same size. Let T(n) denote the time required for sorting an array of n elements using quick sort. Thus,

O(n) partition time $O(n^2)$ worst-case time

 $O(n \log n)$ best-case time

recursive quick sort on two subarrays
$$T(n) = T\left(\frac{n}{2}\right) + T\left(\frac{n}{2}\right) + n.$$

Similar to the merge-sort analysis, $T(n) = O(n \log n)$.

 $O(n \log n)$ average-case time

On the average, the pivot will not divide the array into two parts of the same size or one empty part each time. Statistically, the sizes of the two parts are very close. Therefore, the average time is $O(n \log n)$. The exact average-case analysis is beyond the scope of this book.

Both merge and quick sorts employ the divide-and-conquer approach. For merge sort, the bulk of the work is to merge two sublists, which takes place *after* the sublists are sorted. For quick sort, the bulk of the work is to partition the list into two sublists, which takes place *before* the sublists are sorted. Merge sort is more efficient than quick sort in the worst case, but the two are equally efficient in the average case. Merge sort requires a temporary array for sorting two subarrays. Quick sort does not need additional array space. Thus, quick sort is more space efficient than merge sort.

- **23.5.1** Describe how quick sort works. What is the time complexity for a quick sort?
- **23.5.2** Why is quick sort more space efficient than merge sort?
- **23.5.3** Use Figure 23.7 as an example to show how to apply a quick sort on {45, 11, 50, 59, 60, 2, 4, 7, 10}.
- **23.5.4** If lines 37–38 in the QuickSort program is removed, will it still work? Give a counter example to show that it will not work.

23.6 Heap Sort

A heap sort uses a binary heap. It first adds all the elements to a heap and then removes the largest elements successively to obtain a sorted list.

Heap sorts use a binary heap, which is a complete binary tree. A binary tree is a hierarchical structure. It either is empty or it consists of an element, called the *root*, and two distinct binary trees, called the *left subtree* and *right subtree*. The *length* of a path is the number of the edges in the path. The *depth* of a node is the length of the path from the root to the node. A node is called a *leaf* if it does not have subtrees.

A binary heap is a binary tree with the following properties:

- Shape property: It is a complete binary tree.
- Heap property: Each node is greater than or equal to any of its children.

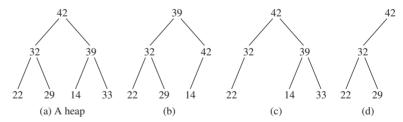

FIGURE 23.9 A binary heap is a special complete binary tree.

complete binary tree

A binary tree is *complete* if each of its levels is full, except that the last level may not be full and all the leaves on the last level are placed leftmost. For example, in Figure 23.9, the binary trees in (a) and (b) are complete, but the binary trees in (c) and (d) are not complete. Further, the binary tree in (a) is a heap, but the binary tree in (b) is not a heap because the root (39) is less than its right child (42).

Note

Heap is a term with many meanings in computer science. In this chapter, heap means a binary heap.

.

Pedagogical Note

A heap can be implemented efficiently for inserting keys and deleting the root. For an interactive demo on how a heap works, go to liveexample.pearsoncmg.com/dsanimation/ HeapeBook.html, as shown in Figure 23.10.

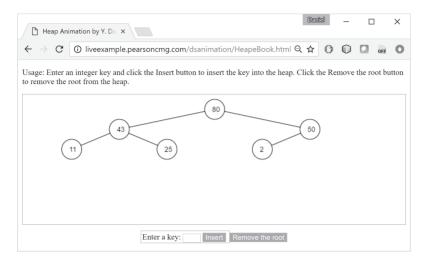

FIGURE 23.10 The heap animation tool enables you to insert a key and delete the root visually. *Source*: Copyright © 1995–2016 Oracle and/or its affiliates. All rights reserved. Used with permission.

23.6.1 Storing a Heap

A heap can be stored in an **ArrayList** or an array if the heap size is known in advance. The heap in Figure 23.11a can be stored using the array in Figure 23.11b. The root is at position 0, and its two children are at positions 1 and 2. For a node at position i, its left child is at position 2i + 1, its right child is at position 2i + 2, and its parent is (i - 1)/2. For example, the node for element 39 is at position 4, so its left child (element 14) is at 9 (2 × 4 + 1), its right child (element 33) is at $10 (2 \times 4 + 2)$, and its parent (element 42) is at 1 (4 - 1)/2).

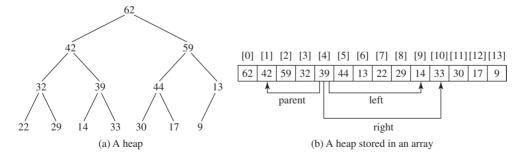

FIGURE 23.11 A binary heap can be implemented using an array.

23.6.2 Adding a New Node

To add a new node to the heap, first add it to the end of the heap then rebuild the tree as follows:

```
Let the last node be the current node;
while (the current node is greater than its parent) {
   Swap the current node with its parent;
   Now the current node is one level up;
}
```

Suppose a heap is initially empty. That heap is shown in Figure 23.12, after adding numbers 3, 5, 1, 19, 11, and 22 in this order.

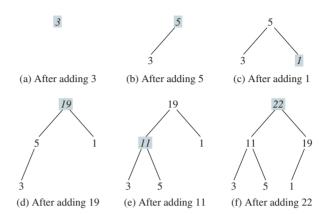

FIGURE 23.12 Elements 3, 5, 1, 19, 11, and 22 are inserted into the heap.

Now consider adding 88 into the heap. Place the new node 88 at the end of the tree, as shown in Figure 23.13a. Swap 88 with 19, as shown in Figure 23.13b. Swap 88 with 22, as shown in Figure 23.13c.

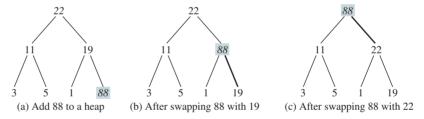

FIGURE 23.13 Rebuild the heap after adding a new node.

23.6.3 Removing the Root

Often you need to remove the maximum element, which is the root in a heap. After the root is removed, the tree must be rebuilt to maintain the heap property. The algorithm for rebuilding the tree can be described as follows:

```
Move the last node to replace the root;
Let the root be the current node;
while (the current node has children and the current node is
smaller than one of its children) {
Swap the current node with the larger of its children;
Now the current node is one level down;
}
```

Figure 23.14 shows the process of rebuilding a heap after the root 62 is removed from Figure 23.11a. Move the last node 9 to the root, as shown in Figure 23.14a. Swap 9 with 59, as shown in Figure 23.14b; swap 9 with 44, as shown in Figure 23.14c; and swap 9 with 30, as shown in Figure 23.14d.

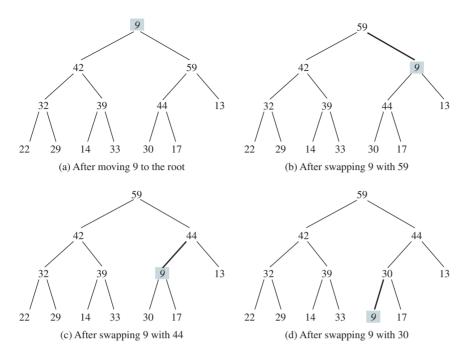

FIGURE 23.14 Rebuild the heap after the root 62 is removed.

Figure 23.15 shows the process of rebuilding a heap after the root 59 is removed from Figure 23.14d. Move the last node 17 to the root, as shown in Figure 23.15a. Swap 17 with 44, as shown in Figure 23.15b, then swap 17 with 30, as shown in Figure 23.15c.

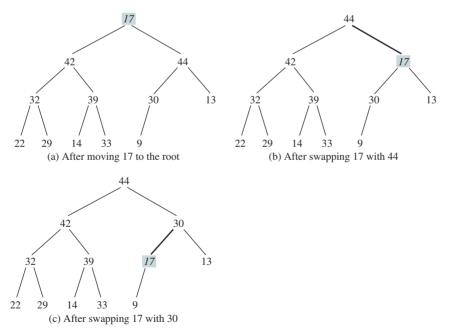

FIGURE 23.15 Rebuild the heap after the root 59 is removed.

23.6.4 The Heap Class

Now you are ready to design and implement the **Heap** class. The class diagram is shown in Figure 23.16. Its implementation is given in Listing 23.9.

```
Heap<E>
-list: java.util.ArrayList<E>
-c: java.util.comparator<E>
+Heap()
+Heap(c: java.util.Comparator<E>)
+Heap(objects: E[])
+add(newObject: E): void
+remove(): E
+getSize(): int
+isEmpty(): boolean
```

Creates a default empty Heap.
Creates an empty heap with the specified comparator.
Creates a Heap with the specified objects.
Adds a new object to the heap.
Removes the root from the heap and returns it.
Returns the size of the heap.
Returns true if the heap is empty.

FIGURE 23.16 The Heap class provides operations for manipulating a heap.

LISTING 23.9 Heap. java

```
public class Heap<E> {
                              private java.util.ArrayList<E> list = new java.util.ArrayList<>();

90
    }
```

A heap is represented using an array list internally (line 2). You can change the array list to other data structures, but the **Heap** class contract will remain unchanged.

The elements in the heap can be compared using a comparator or using a natural order if no comparator is specified.

The no-arg constructor (line 6) creates an empty heap using a natural order for the elements as the comparator. The comparator is created using a lambda expression (line 7).

The **add(E newObject)** method (lines 23–41) appends the object to the tree then swaps the object with its parent if the object is greater than its parent. This process continues until the new object becomes the root or is not greater than its parent.

The **remove()** method (lines 44–79) removes and returns the root. To maintain the heap property, the method moves the last object to the root position and swaps it with its larger child if it is less than the larger child. This process continues until the last object becomes a leaf or is not less than its children.

23.6.5 Sorting Using the **Heap** Class

To sort an array using a heap, first create an object using the **Heap** class, add all the elements to the heap using the add method, and remove all the elements from the heap using the remove method. The elements are removed in descending order. Listing 23.10 gives a program for sorting an array using a heap.

LISTING 23.10 HeapSort.java

```
1 import java.util.Comparator;
                         3 public class HeapSort {
                              /** Heap sort method */
                              public static <E> void heapSort(E[] list) {

                              public static <E> void heapSort(E[] list, Comparator<E> c) {
                        11
                        12
                                // Create a Heap of integers
                        13
                                Heap < E > heap = new Heap <> (c);
                        14
                        15
                                // Add elements to the heap
                                for (int i = 0; i < list.length; i++)</pre>
                        16
                        17
                                  heap.add(list[i]);
                        18
                                // Remove elements from the heap
                        19
                        20
                                for (int i = list.length - 1; i \ge 0; i--)
                        21
                                  list[i] = heap.remove();
                        22
                        23
                              /** A test method */
                        24
                        25
                              public static void main(String[] args) {
                                Integer[] list = \{-44, -5, -3, 3, 3, 1, -4, 0, 1, 2, 4, 5, 53\};
                        26
                        27
                                heapSort(list);
                                for (int i = 0; i < list.length; i++)</pre>
                        28
                        29
                                  System.out.print(list[i] + " ");
                        30
                              }
                        31
                            }
```

```
-44 -5 -4 -3 0 1 1 2 3 3 4 5 53
```

Two heapSort methods are provided here. The heapSort(E[] list) method (line 5) sorts a list in a natural order using the Comparable interface. The heapSort (E[] list, Comparator<E> c) method (line 11) sorts a list using a specified comparator.

23.6.6 Heap Sort Time Complexity

height of a heap

Let us turn our attention to analyzing the time complexity for the heap sort. Let h denote the height for a heap of n elements. The height of a nonempty tree is the length of the path from the root node to its furthest leaf. The height of a tree that contains a single node is 0. Conventionally, the height of an empty tree is -1. Since a heap is a complete binary tree, the first level has 1 (2^0) node, the second level has 2 (2^1) nodes, the kth level has 2^{k-1} nodes, the h level has 2^{h-1} nodes, and the last (h+1)th level has at least 1 and at most 2^h nodes. Therefore,

```
1 + 2 + \cdots + 2^{h-1} < n \le 1 + 2 + \cdots + 2^{h-1} + 2^h
```

That is, heap sort vs. merge sort

$$2^{h} - 1 < n \le 2^{h+1} - 1$$

 $2^{h} < n + 1 \le 2^{h+1}$
 $h < \log(n + 1) \le h + 1$

Thus, $h < \log(n+1)$ and $h \ge \log(n+1) - 1$. Therefore, $\log(n+1) - 1 \le h < \log(n+1)$. Hence, the height of a heap is $O(\log n)$. More precisely, you can prove that $h = |\log n|$ for a non-empty tree.

Since the **add** method traces a path from a leaf to a root, it takes at most h steps to add a new element to the heap. Thus, the total time for constructing an initial heap is $O(n \log n)$ for an array of n elements. Since the **remove** method traces a path from a root to a leaf, it takes at most h steps to rebuild a heap after removing the root from the heap. Since the **remove** method is invoked n times, the total time for producing a sorted array from a heap is $O(n \log n)$.

Both merge and heap sorts require $O(n \log n)$ time. A merge sort requires a temporary array for merging two subarrays; a heap sort does not need additional array space. Therefore, a heap sort is more space efficient than a merge sort.

- **23.6.1** What is a complete binary tree? What is a heap? Describe how to remove the root from a heap and how to add a new object to a heap.
- **23.6.2** Add the elements **4**, **5**, **1**, **2**, **9**, and **3** into a heap in this order. Draw the diagrams to show the heap after each element is added.
- **23.6.3** Show the steps of creating a heap using {45, 11, 50, 59, 60, 2, 4, 7, 10}.
- **23.6.4** Show the heap after the root in the heap in Figure 23.15c is removed.
- **23.6.5** Given the following heap, show the steps of removing all nodes from the heap.

- **23.6.6** Which of the following statements are wrong?
 - 1 Heap<0bject> heap1 = new Heap<>();
 - 2 Heap<Number> heap2 = new Heap<>();
 - 3 Heap<BigInteger> heap3 = new Heap<>();
 - 4 Heap<Calendar> heap4 = new Heap<>();
 - 5 Heap<String> heap5 = new Heap<>();
- **23.6.7** What is the return value from invoking the **remove** method if the heap is empty?
- **23.6.8** What is the time complexity of inserting a new element into a heap, and what is the time complexity of deleting an element from a heap?
- **23.6.9** What is the height of a nonempty heap? What is the height of a heap with 16, 17, and 512 elements? If the height of a heap is 5, what is the maximum number of nodes in the heap?

23.7 Bucket and Radix Sorts

Bucket and radix sorts are efficient for sorting integers.

All sort algorithms discussed so far are general sorting algorithms that work for any types of keys (e.g., integers, strings, and any comparable objects). These algorithms sort the elements

 $O(n \log n)$ worst-case time

bucket sort

by comparing their keys. It has been proven that no sorting algorithms based on comparisons can perform better than $O(n \log n)$. However, if the keys are integers, you can use a bucket sort without having to compare the keys.

The bucket sort algorithm works as follows. Assume the keys are in the range from 0 to t. We need t + 1 buckets labeled 0, 1, ..., and t. If an element's key is i, the element is put into the bucket i. Each bucket holds the elements with the same key value.

You can use an ArrayList to implement a bucket. The bucket-sort algorithm for sorting a list of elements can be described as follows:

```
public static void bucketSort(E[] list) {
  E[] bucket = (E[]) new java.util.ArrayList[t+1];
  // Distribute the elements from list to buckets
  for (int i = 0; i < list.length; i++) {</pre>
    int key = list[i].getKey(); // Assume element has the getKey() method
    if (bucket[key] == null)
      bucket[key] = new java.util.ArrayList<>();
    bucket[key].add(list[i]);
  }
  // Now move the elements from the buckets back to list
  int k = 0; // k is an index for list
  for (int i = 0; i < bucket.length; i++) {</pre>
    if (bucket[i] != null) {
      for (int j = 0; j < bucket[i].size(); j++)</pre>
        list[k++] = bucket[i].get(j);
  }
}
```

Clearly, it takes O(n + t) time to sort the list and uses O(n + t) space, where n is the list size. Note if t is too large, using the bucket sort is not desirable. Instead, you can use a radix sort. The radix sort is based on the bucket sort, but a radix sort uses only 10 buckets.

It is worthwhile to note a bucket sort is *stable*, meaning that if two elements in the original list have the same key value, their order is not changed in the sorted list. That is, if element e_1 and element e_2 have the same key and e_1 precedes e_2 in the original list, e_1 still precedes e_2 in the sorted list.

Assume the keys are positive integers. The idea for the radix sort is to divide the keys into subgroups based on their radix positions. It applies a bucket sort repeatedly for the key values on radix positions, starting from the least-significant position.

Consider sorting the elements with the following keys:

```
331, 454, 230, 34, 343, 45, 59, 453, 345, 231, 9
```

Apply the bucket sort on the last radix position, and the elements are put into the buckets as follows:

```
230
            331
                                    343
                                                  454
                                                               45
```

```
59
              231
                                      453
                                                      34
                                                                 345
                                                                                                                     9
                                    bucket[3]
                                                 bucket[4]
                                                             bucket[5]
                                                                                      bucket[7]
bucket[0]
            bucket[1]
                        bucket[2]
                                                                          bucket[6]
                                                                                                  bucket[8]
                                                                                                               bucket[9]
```

stable

radix sort

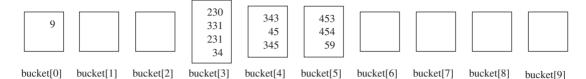

radix sort on Companion Website

queue

After collecting the elements from the buckets, the elements are in the following order:

Apply the bucket sort on the second-to-last radix position, and the elements are put into the queue buckets as follows:

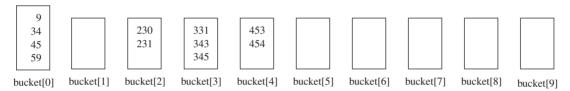

After collecting the elements from the buckets, the elements are in the following order:

(Note 9 is 009.)

Apply the bucket sort on the third-to-last radix position, and the elements are put into the buckets as follows:

queue

After collecting the elements from the buckets, the elements are in the following order:

The elements are now sorted.

Radix sort takes O(dn) time to sort n elements with integer keys, where d is the maximum number of the radix positions among all keys.

- **23.7.1** Can you sort a list of strings using a bucket sort?
- **23.7.2** Show how the radix sort works using the numbers **454**, **34**, **23**, **43**, **74**, **86**, and **76**.

23.8 External Sort

You can sort a large amount of data using an external sort.

All the sort algorithms discussed in the preceding sections assume all the data to be sorted are available at one time in internal memory, such as in an array. To sort data stored in an external file, you must first bring the data to the memory then sort it internally. However, if the file is too large, all the data in the file cannot be brought to memory at one time. This section discusses how to sort data in a large external file. This is called an *external sort*.

external sort

For simplicity, assume two million **int** values are stored in a binary file named **largedata**.**dat**. This file was created using the program in Listing 23.11.

A variation of merge sort can be used to sort this file in two phases:

Phase I: Repeatedly bring data from the file to an array, sort the array using an internal sorting algorithm, and output the data from the array to a temporary file. This process is shown in Figure 23.17. Ideally, you want to create a large array, but its maximum size depends on how much memory is allocated to the JVM by the operating system. Assume the maximum array size is 100,000 int values. In the temporary file, every 100,000 int values are sorted. They are denoted as S_1, S_2, \ldots , and S_k , where the last segment, S_k , may contain less than 100,000 values.

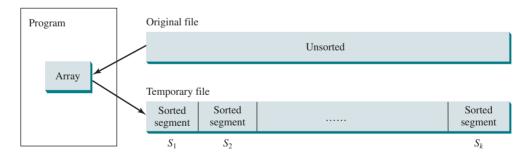

FIGURE 23.17 The original file is sorted in segments.

Phase II: Merge a pair of sorted segments (e.g., S_1 with S_2 , S_3 with S_4 , ..., and so on) into a larger sorted segment and save the new segment into a new temporary file. Continue the same process until only one sorted segment results. Figure 23.18 shows how to merge eight segments.

Note

It is not necessary to merge two successive segments. For example, you can merge S_1 with S_5 , S_2 with S_6 , S_3 with S_7 , and S_4 with S_8 , in the first merge step. This observation is useful in implementing Phase II efficiently.

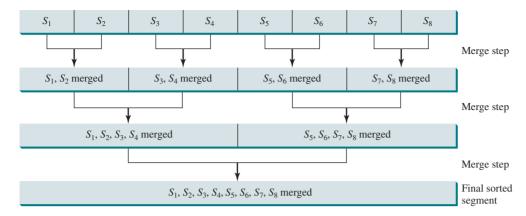

FIGURE 23.18 Sorted segments are merged iteratively.

23.8.1 Implementing Phase I

Listing 23.12 gives the method that reads each segment of data from a file, sorts the segment, and stores the sorted segments into a new file. The method returns the number of segments.

LISTING 23.12 Creating Initial Sorted Segments

```
/** Sort original file into sorted segments */
    private static int initializeSegments
 3
        (int segmentSize, String originalFile, String f1)
 4
        throws Exception {
 5
      int[] list = new int[segmentSize];
 6
      DataInputStream input = new DataInputStream(
 7
        new BufferedInputStream(new FileInputStream(originalFile)));
                                                                                 original file
 8
      DataOutputStream output = new DataOutputStream(
9
        new BufferedOutputStream(new FileOutputStream(f1)));
                                                                                 file with sorted segments
10
      int numberOfSegments = 0;
11
      while (input.available() > 0) {
12
13
        numberOfSegments++;
14
        int i = 0:
        for ( ; input.available() > 0 && i < segmentSize; i++) {</pre>
15
16
          list[i] = input.readInt();
17
18
        // Sort an array list[0..i-1]
19
20
        java.util.Arrays.sort(list, 0, i);
                                                                                 sort a segment
21
22
        // Write the array to f1.dat
23
        for (int j = 0; j < i; j++) {
24
          output.writeInt(list[j]);
                                                                                 output to file
25
        }
      }
26
                                                                                 close file
27
28
      input.close();
29
      output.close();
30
31
      return numberOfSegments;
                                                                                 return # of segments
32
    }
```

The method creates an array with the maximum size in line 5, a data input stream for the original file in line 6, and a data output stream for a temporary file in line 8. Buffered streams are used to improve performance.

Lines 14–17 read a segment of data from the file into the array. Line 20 sorts the array. Lines 23–25 write the data in the array to the temporary file.

The number of segments is returned in line 31. Note every segment has MAX ARRAY SIZE number of elements except the last segment, which may have fewer elements.

23.8.2 Implementing Phase II

In each merge step, two sorted segments are merged to form a new segment. The size of the new segment is doubled. The number of segments is reduced by half after each merge step. A segment is too large to be brought to an array in memory. To implement a merge step, copy half the number of segments from the file f1.dat to a temporary file f2.dat. Then, merge the first remaining segment in f1.dat with the first segment in f2.dat into a temporary file named **f3.dat**, as shown in Figure 23.19.

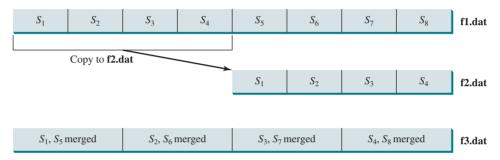

FIGURE 23.19 Sorted segments are merged iteratively.

Note

fl.dat may have one segment more than f2.dat. If so, move the last segment into f3.dat after the merge.

Listing 23.13 gives a method that copies the first half of the segments in **f1.dat** to **f2.dat**. Listing 23.14 gives a method that merges a pair of segments in **f1.dat** and **f2.dat**. Listing 23.15 gives a method that merges two segments.

Copying First Half Segments **LISTING 23.13**

```
private static void copyHalfToF2(int numberOfSegments,
2
       int segmentSize, DataInputStream f1, DataOutputStream f2)
3
       throws Exception {
4
     for (int i = 0; i < (numberOfSegments / 2) * segmentSize; i++) {</pre>
5
       f2.writeInt(f1.readInt());
6
7
  }
```

Merging All Segments **LISTING 23.14**

```
private static void mergeSegments(int numberOfSegments,
input stream f1 and f2
                         2
                                 int segmentSize, DataInputStream f1, DataInputStream f2,
                         3
output stream f3
                                 DataOutputStream f3) throws Exception {
                         4
                               for (int i = 0; i < numberOfSegments; i++) {</pre>
                         5
                                 mergeTwoSegments(segmentSize, f1, f2, f3);
merge two segments
                         6
                         7
                         8
                               // If f1 has one extra segment, copy it to f3
                         9
extra segment in f1?
                               while (f1.available() > 0) {
                        10
                                 f3.writeInt(f1.readInt());
                        11
```

12

input stream f1 output stream f2

segments copied

LISTING 23.15 Merging Two Segments

```
private static void mergeTwoSegments(int segmentSize,
        DataInputStream f1, DataInputStream f2,
                                                                                    input stream f1 and f2
        DataOutputStream f3) throws Exception {
 3
                                                                                    output stream f3
 4
      int intFromF1 = f1.readInt();
                                                                                    read from f1
 5
      int intFromF2 = f2.readInt():
                                                                                    read from f2
 6
      int f1Count = 1;
 7
      int f2Count = 1;
 8
9
      while (true) {
10
        if (intFromF1 < intFromF2) {</pre>
           f3.writeInt(intFromF1);
11
                                                                                    write to f3
12
           if (f1.available() == 0 || f1Count++ >= segmentSize) {
13
             f3.writeInt(intFromF2);
14
             break:
                                                                                    segment in f1 finished
15
           }
16
           else {
17
             intFromF1 = f1.readInt();
18
19
        }
20
        else {
21
           f3.writeInt(intFromF2);
                                                                                    write to f3
22
          if (f2.available() == 0 || f2Count++ >= segmentSize) {
23
             f3.writeInt(intFromF1);
24
             break:
                                                                                    segment in f2 finished
25
           }
26
           else {
27
             intFromF2 = f2.readInt();
28
           }
29
        }
30
      }
31
32
      while (f1.available() > 0 && f1Count++ < segmentSize) {</pre>
                                                                                    remaining f1 segment
33
        f3.writeInt(f1.readInt());
34
35
36
      while (f2.available() > 0 && f2Count++ < segmentSize) {</pre>
                                                                                    remaining f2 segment
37
        f3.writeInt(f2.readInt());
38
39 }
```

23.8.3 Combining Two Phases

Listing 23.16 gives the complete program for sorting **int** values in **largedata.dat** and storing the sorted data in **sortedfile.dat**.

LISTING 23.16 SortLargeFile.java

```
1
   import java.io.*;
2
   public class SortLargeFile {
      public static final int MAX_ARRAY_SIZE = 100000;
                                                                              max array size
5
      public static final int BUFFER_SIZE = 100000;
                                                                              I/O stream buffer size
6
7
      public static void main(String[] args) throws Exception {
8
        // Sort largedata.dat to sortedfile.dat
9
        sort("largedata.dat", "sortedfile.dat");
10
11
        // Display the first 100 numbers in the sorted file
```

```
12
                                 displayFile("sortedfile.dat");
                        13
                               }
create initial segments
                        14
                        15
                               /** Sort data in source file and into target file */
                               public static void sort(String sourcefile, String targetfile)
merge recursively
                        16
                                   throws Exception {
                        17
                                 // Implement Phase 1: Create initial segments
                        18
                        19
                                 int numberOfSegments =
                        20
                                   initializeSegments(MAX_ARRAY_SIZE, sourcefile, "f1.dat");
                        21
                        22

109 }
```

0 1 1 1 2 2 2 3 3 4 5 6 8 8 9 9 9 10 10 11...(omitted)

Before you run this program, first run Listing 23.11, CreateLargeFile.java, to create the file largedata.dat. Invoking sort("largedata.dat", "sortedfile.dat") (line 9) reads data from largedata.dat and writes sorted data to sortedfile.dat. Invoking display-File("sortedfile.dat") (line 12) displays the first 100 numbers in the specified file. Note the files are created using binary I/O. You cannot view them using a text editor such as Notepad.

The **sort** method first creates initial segments from the original array and stores the sorted segments in a new file, **f1.dat** (lines 19–20), then produces a sorted file in **targetfile** (lines 23–24).

The **merge** method

```
merge(int numberOfSegments, int segmentSize,
   String f1, String f2, String f3, String targetfile)
```

merges the segments in f1 into f3 using f2 to assist the merge. The merge method is invoked recursively with many merge steps. Each merge step reduces the numberOfSegments by half and doubles the sorted segment size. After the completion of one merge step, the next merge

step merges the new segments in **f3** to **f2** using **f1** to assist the merge. The statement to invoke the new merge method is

```
merge((numberOfSegments + 1) / 2, segmentSize * 2,
f3, f1, f2, targetfile);
```

The numberOfSegments for the next merge step is (numberOfSegments + 1) / 2. For example, if numberOfSegments is 5, numberOfSegments is 3 for the next merge step because every two segments are merged but one is left unmerged.

The recursive **merge** method ends when **numberOfSegments** is 1. In this case, **f1** contains sorted data. File **f1** is renamed to **targetfile** (line 45).

23.8.4 External Sort Complexity

In the external sort, the dominating cost is that of I/O. Assume n is the number of elements to be sorted in the file. In Phase I, n number of elements are read from the original file and output to a temporary file. Therefore, the I/O for Phase I is O(n).

In Phase II, before the first merge step, the number of sorted segments is $\frac{n}{c}$, where c is MAX_ARRAY_SIZE. Each merge step reduces the number of segments by half. Thus, after the first merge step, the number of segments is $\frac{n}{2c}$. After the second merge step, the number of segments is $\frac{n}{2^3c}$, and after the third merge step the number of segments is $\frac{n}{2^3c}$. After $\log\left(\frac{n}{c}\right)$ merge steps, the number of segments is reduced to 1. Therefore, the total number of merge steps is $\log\left(\frac{n}{c}\right)$.

In each merge step, half the number of segments are read from file **f1** then written into a temporary file **f2**. The remaining segments in **f1** are merged with the segments in **f2**. The number of I/Os in each merge step is O(n). Since the total number of merge steps is $\log\left(\frac{n}{c}\right)$, the total number of I/Os is

$$O(n) \times \log\left(\frac{n}{c}\right) = O(n \log n)$$

Therefore, the complexity of the external sort is $O(n \log n)$.

- **23.8.1** Describe how external sort works. What is the complexity of the external sort algorithm?
- **23.8.2** Ten numbers {2, 3, 4, 0, 5, 6, 7, 9, 8, 1} are stored in the external file **largedata.dat**. Trace the **SortLargeFile** program by hand with **MAX_ARRAY_SIZE** 2.

KEY TERMS

bubble sort 912	heap sort 922
bucket sort 930	height of a heap 928

external sort 931	quick sort 918
heap 922	radix sort 930

CHAPTER SUMMARY

- 1. The worst-case complexity for a selection sort, insertion sort, bubble sort, and quick sort is $O(n^2)$.
- **2.** The average- and worst-case complexity for a *merge sort* is $O(n \log n)$. The average time for a quick sort is also $O(n \log n)$.
- 3. Heaps are a useful data structure for designing efficient algorithms such as sorting. You learned how to define and implement a heap class, and how to insert and delete elements to/from a heap.
- **4.** The time complexity for a *heap sort* is $O(n \log n)$.
- 5. Bucket and radix sorts are specialized sorting algorithms for integer keys. These algorithms sort keys using buckets rather than by comparing keys. They are more efficient than general sorting algorithms.
- **6.** A variation of the merge sort—called an *external sort*—can be applied to sort large amounts of data from external files.

Quiz

Answer the guiz for this chapter online at the book Companion Website.

PROGRAMMING EXERCISES

MyProgrammingLab[®]

Sections 23.3-23.5

23.1 (Generic bubble sort) Write the following two generic methods using bubble sort. The first method sorts the elements using the Comparable interface, and the second uses the **Comparator** interface.

```
public static <E extends Comparable<E>>
 void bubbleSort(E[] list)
public static <E> void bubbleSort(E[] list,
 Comparator<? super E> comparator)
```

23.2 (Generic merge sort) Write the following two generic methods using merge sort. The first method sorts the elements using the Comparable interface and the second uses the **Comparator** interface.

```
public static <E extends Comparable<E>>
 void mergeSort(E[] list)
public static <E> void mergeSort(E[] list,
 Comparator<? super E> comparator)
```

23.3 (Generic quick sort) Write the following two generic methods using quick sort. The first method sorts the elements using the Comparable interface, and the second uses the **Comparator** interface.

```
public static <E extends Comparable<E>>
 void quickSort(E[] list)
public static <E> void quickSort(E[] list,
 Comparator<? super E> comparator)
```

- 23.4 (Improve quick sort) The quick-sort algorithm presented in the book selects the first element in the list as the pivot. Revise it by selecting the median among the first, middle, and the last elements in the list.
- *23.5 (Modify merge sort) Rewrite the mergeSort method to recursively sort the first half of the array and the second half of the array without creating new temporary arrays, then merge the two into a temporary array and copy its contents to the original array, as shown in Figure 23.6b.
- 23.6 (Generic insertion sort) Write the following two generic methods using insertion sort. The first method sorts the elements using the Comparable interface and the second uses the Comparator interface.

```
public static <E extends Comparable<E>> voidinsertionSort
(E[] list)
public static <E void insertionSort(E[] list,</pre>
Comparator<?super E> comparator)
```

Section 23.6

- 23.7 (Min-heap) The heap presented in the text is also known as a max-heap, in which each node is greater than or equal to any of its children. A min-heap is a heap in which each node is less than or equal to any of its children. Min-heaps are often used to implement priority queues. Revise the **Heap** class in Listing 23.9 to implement a min-heap.
- 23.8 (Generic insertion sort) Write the following two generic methods using insertion sort. The first method sorts the elements using the Comparable interface, and the second uses the **Comparator** interface.

```
public static <E extends Comparable<E>>
  void insertionSort(E[] list)
public static <E> void insertionSort(E[] list,
  Comparator<? super E> comparator)
```

*23.9 (Generic heap sort) Write the following two generic methods using heap sort. The first method sorts the elements using the **Comparable** interface, and the second uses the **Comparator** interface. (*Hint*: Use the **Heap** class in Programming Exercise 23.5.)

```
public static <E extends Comparable<E>>
 void heapSort(E[] list)
public static <E> void heapSort(E[] list,
 Comparator<? super E> comparator)
```

**23.10 (Heap visualization) Write a program that displays a heap graphically, as shown in Figure 23.10. The program lets you insert and delete an element from the heap.

max-heap min-heap

23.11 (Heap clone and equals) Implement the clone and equals method in the Heap class.

> Use the template at liveexample.pearsoncmg.com/test/Exercise23_11. txt for your code.

Section 23.7

- *23.12 (Radix sort) Write a program that randomly generates 1,200,000 integers and sorts them using radix sort.
- *23.13 (Execution time for sorting) Write a program that obtains the execution time of selection sort, bubble sort, merge sort, quick sort, heap sort, and radix sort for input size 60,000, 120,000, 180,000, 240,000, 300,000, and 360,000. Your program should create data randomly and print a table like this:

Array size	Selection Sort	Bubble Sort	Merge Sort	Quick Sort	Heap Sort	Radix Sort	
60,000							
120,000							
180,000							
240,000							
300,000							
360,000							

(*Hint*: You can use the following code template to obtain the execution time.)

```
long startTime = System.currentTimeMillis();
perform the task:
long endTime = System.currentTimeMillis();
long executionTime = endTime - startTime;
```

The text gives a recursive quick sort. Write a nonrecursive version in this exercise

Section 23.8

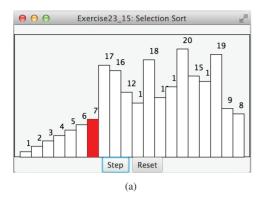

*23.14 (Execution time for external sorting) Write a program that obtains the execution time of external sorts for integers of size 6,000,000, 12,000,000, 18,000,000, 24,000,000, 30,000,000, and 36,000,000. Your program should print a table like this:

File size	6,000,000	12,000,000	18,000,000	24,000,000	30,000,000	36,000,000
Time						

Comprehensive

*23.15 (Selection-sort animation) Write a program that animates the selection-sort algorithm. Create an array that consists of 20 distinct numbers from 1 to 20 in a random order. The array elements are displayed in a histogram, as shown in Figure 23.20a. Clicking the *Step* button causes the program to perform an iteration of the outer loop in the algorithm and repaints the histogram for the new array. Color the last bar in the sorted subarray. When the algorithm is finished, display a message to inform the user. Clicking the Reset button creates a new random array for a new start. (You can easily modify the program to animate the insertion algorithm.)

942 Chapter 23 Sorting

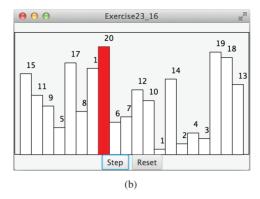

FIGURE 23.20 (a) The program animates selection sort. *Source*: Copyright © 1995–2016 Oracle and/or its affiliates. All rights reserved. Used with permission. (b) The program animates bubble sort.

- *23.16 (Bubble-sort animation) Write a program that animates the bubble sort algorithm. Create an array that consists of 25 distinct numbers from 1 to 25 in a random order. The array elements are displayed in a histogram, as shown in Figure 23.20b. Clicking the Step button causes the program to perform one comparison in the algorithm and repaints the histogram for the new array. Color the bar that represents the number being considered in the swap. When the algorithm is finished, display a message to inform the user. Clicking the Reset button creates a new random array for a new start.
- *23.17 (Radix-sort animation) Write a program that animates the radix-sort algorithm. Create an array that consists of 20 random numbers from 0 to 1,000. The array elements are displayed, as shown in Figure 23.21. Clicking the Step button causes the program to place a number in a bucket. The number that has just been placed is displayed in red. Once all the numbers are placed in the buckets, clicking the Step button collects all the numbers from the buckets and moves them back to the array. When the algorithm is finished, clicking the Step button displays a message to inform the user. Clicking the Reset button creates a new random array for a new start.

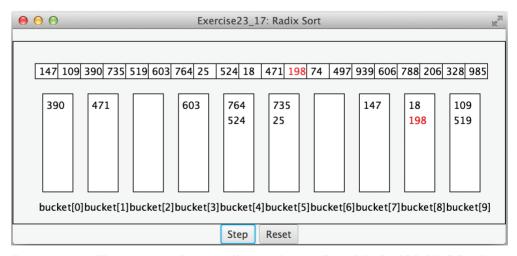

FIGURE 23.21 The program animates radix sort. *Source*: Copyright © 1995–2016 Oracle and/or its affiliates. All rights reserved. Used with permission.

*23.18 (Merge animation) Write a program that animates the merge of two sorted lists. Create two arrays, list1 and list2, each of which consists of 8 random numbers from 1 to 999. The array elements are displayed, as shown in Figure 23.22a. Clicking the *Step* button causes the program to move an element from list1 or 1ist2 to temp. Clicking the Reset button creates two new random arrays for a new start. When the algorithm is finished, clicking the Step button displays a message to inform the user.

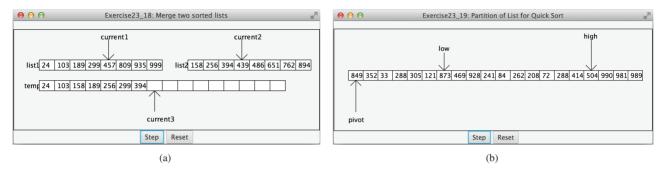

FIGURE 23.22 The program animates a merge of two sorted lists. Source: Copyright © 1995–2016 Oracle and/or its affiliates. All rights reserved. Used with permission. (b) The program animates a partition for quick sort.

*23.19 (Quick-sort partition animation) Write a program that animates the partition for a quick sort. The program creates a list that consists of 25 random numbers from 1 to 999. The list is displayed, as shown in Figure 23.22b. Clicking the Step button causes the program to move low to the right or high to the left, or swap the elements at low and high. Clicking the *Reset* button creates a new list of random numbers for a new start. When the algorithm is finished, clicking the *Step* button displays a message to inform the user.
